FILING RECEIPT

OC000000014419126

Date Mailed: 11/22/2004

Receipt is acknowledged of this provisional Patent Application. It will not be examined for patentability and will become abandoned not later than twelve months after its filing date. Be sure to provide the U.S. APPLICATION NUMBER, FILING DATE, NAME OF APPLICANT, and TITLE OF INVENTION when inquiring about this application. Fees transmitted by check or draft are subject to collection. Please verify the accuracy of the data presented on this receipt. If an error is noted on this Filing Receipt, please write to the Office of Initial Patent Examination's Filing Receipt Corrections, facsimile number 703-746-9195. Please provide a copy of this Filing Receipt with the changes noted thereon. If you received a "Notice to File Missing Parts" for this application, please submit any corrections to this Filing Receipt with your reply to the Notice. When the USPTO processes the reply to the Notice, the USPTO will generate another Filing Receipt incorporating the requested corrections (if appropriate).

**LICENSE FOR FOREIGN FILING UNDER
Title 35, United States Code, Section 184
Title 37, Code of Federal Regulations, 5.11 & 5.15**

GRANTED

The applicant has been granted a license under 35 U.S.C. 184, if the phrase "IF REQUIRED, FOREIGN FILING LICENSE GRANTED" followed by a date appears on this form. Such licenses are issued in all applications where the conditions for issuance of a license have been met, regardless of whether or not a license may be required as set forth in 37 CFR 5.15. The scope and limitations of this license are set forth in 37 CFR 5.15(a) unless an earlier license has been issued under 37 CFR 5.15(b). The license is subject to revocation upon written notification. The date indicated is the effective date of the license, unless an earlier license of similar scope has been granted under 37 CFR 5.13 or 5.14.

This license is to be retained by the licensee and may be used at any time on or after the effective date thereof unless it is revoked. This license is automatically transferred to any related applications(s) filed under 37 CFR 1.53(d). This license is not retroactive.

The grant of a license does not in any way lessen the responsibility of a licensee for the security of the subject matter as imposed by any Government contract or the provisions of existing laws relating to espionage and the national security or the export of technical data. Licensees should apprise themselves of current regulations especially with respect to certain countries, of other agencies, particularly the Office of Defense Trade Controls, Department of State (with respect to Arms, Munitions and Implements of War (22 CFR 121-128)); the Office of Export Administration, Department of Commerce (15 CFR 370.10 (j)); the Office of Foreign Assets Control, Department of Treasury (31 CFR Parts 500+) and the Department of Energy.

NOT GRANTED

No license under 35 U.S.C. 184 has been granted at this time, if the phrase "IF REQUIRED, FOREIGN FILING LICENSE GRANTED" DOES NOT appear on this form. Applicant may still petition for a license under 37 CFR 5.12, if a license is desired before the expiration of 6 months from the filing date of the application. If 6 months has lapsed from the filing date of this application and the licensee has not received any indication of a secrecy order under 35 U.S.C. 181, the licensee may foreign file the application pursuant to 37 CFR 5.15(b).

THIS PAGE BLANK (USPTO)

5 **COATING COMPOSITIONS FOR CANS
AND METHODS OF COATING**

Background

10 A wide variety of coatings have been used to coat the surfaces of packaging
articles (e.g., food and beverage cans). For example, metal cans are sometimes
coated using "coil coating" or "sheet coating" operations, i.e., a planar coil or sheet
of a suitable substrate (e.g., steel or aluminum metal) is coated with a suitable
composition and hardened (e.g., cured). The coated substrate then is formed into the
can end or body. Alternatively, liquid coating compositions may be applied (e.g., by
15 spraying, dipping, rolling, etc.) to the formed article and then hardened (e.g., cured).

 Packaging coatings should preferably be capable of high-speed application to
the substrate and provide the necessary properties when hardened to perform in this
demanding end use. For example, the coating should be safe for food contact, have
excellent adhesion to the substrate, and resist degradation over long periods of time,
20 even when exposed to harsh environments.

 Many current packaging coatings contain mobile or bound bisphenol A
("BPA") or aromatic glycidyl ether compounds or PVC compounds. Although the
balance of scientific evidence available to date indicates that the small trace amounts
of these compounds that might be released from existing coatings does not pose any
25 health risks to humans, these compounds are nevertheless perceived by some people
as being potentially harmful to human health. Consequently, there is a strong desire
to eliminate these compounds from food contact coatings.

 From the foregoing, it will be appreciated that what is needed in the art is a
packaging container (e.g., a food or beverage can) that is coated with a composition
30 that does not contain extractable quantities of such compounds.

Summary

This invention provides a coating composition for a food or beverage can that includes an emulsion polymerized latex polymer. This polymer is formed by combining an ethylenically unsaturated monomer component with an aqueous
5 dispersion of a salt of an acid- or anhydride-functional polymer (i.e., an acid group- or anhydride group-containing polymer) and an amine, preferably, a tertiary amine, and then polymerizing the monomer component.

The ethylenically unsaturated monomer component is preferably a mixture of monomers. At least one of the monomers in the mixture is preferably an alpha, beta-
10 unsaturated monomer, and at least one monomer is preferably an oxirane functional monomer. More preferably, at least one of the monomers in the mixture is an oxirane group-containing alpha, beta-ethylenically unsaturated monomer.

In one embodiment, a method of preparing a food or beverage can is provided. The method includes: forming a composition that includes an emulsion
15 polymerized latex polymer, including: forming a salt of an acid- or anhydride-functional polymer and an amine in a carrier comprising water (and an optional organic solvent) to form an aqueous dispersion; combining an ethylenically unsaturated monomer component with the aqueous dispersion; and polymerizing the ethylenically unsaturated monomer component in the presence of the aqueous
20 dispersion to form an emulsion polymerized latex polymer; and applying the composition including the emulsion polymerized latex polymer to a metal substrate prior to or after forming the metal substrate into a food or beverage can or portion thereof.

In another embodiment, the method includes: forming a composition
25 including an emulsion polymerized latex polymer, including: forming a salt of an acid- or anhydride-functional polymer and a tertiary amine in a carrier comprising water (and an optional organic solvent) to form an aqueous dispersion; combining an ethylenically unsaturated monomer component comprising 0.1 wt-% to 30 wt-% of an oxirane-functional alpha, beta-ethylenically unsaturated monomer with the
30 aqueous dispersion, based on the weight of the monomer component; and polymerizing the ethylenically unsaturated monomer component in the presence of the aqueous dispersion to form an emulsion polymerized latex polymer; and applying the composition comprising the emulsion polymerized latex polymer to a

metal substrate prior to or after forming the metal substrate into a food or beverage can or portion thereof.

In certain embodiments, the composition can include an organic solvent in the aqueous dispersion. In certain embodiments, the method can include removing
5 at least a portion of the organic solvent, if present, from the aqueous dispersion.

In certain embodiments, applying the composition to a metal substrate includes applying the composition to the metal substrate in the form of a planar coil or sheet, hardening the emulsion polymerized latex polymer, and forming the substrate into a food or beverage can or portions thereof. In certain embodiments,
10 applying the composition to a metal substrate comprises applying the composition to the metal substrate after the metal substrate is formed into a can or portion thereof.

In certain embodiments, forming the substrate into a can or portion thereof includes forming the substrate into a can end or a can body. In certain embodiments, the can is a 2-piece drawn food can, 3-piece food can, food can end, drawn and
15 ironed food or beverage can, beverage can end, and the like. The metal substrate can be steel or aluminum.

In certain embodiments, combining an ethylenically unsaturated monomer component with the aqueous dispersion includes adding the ethylenically unsaturated monomer component to the aqueous dispersion. Preferably, the
20 ethylenically unsaturated monomer component is added incrementally to the aqueous dispersion.

In certain embodiments, the ethylenically unsaturated monomer component includes a mixture of monomers. Preferably, the mixture of monomers includes at least one oxirane functional group-containing monomer, and more preferably, at
25 least one oxirane functional group-containing alpha, beta-ethylenically unsaturated monomer. In certain embodiments, the oxirane functional group-containing monomer is present in the ethylenically unsaturated monomer component in an amount of at least 0.1 wt-%, based on the weight of the monomer mixture. In certain embodiments, the oxirane functional group-containing monomer is present in
30 the ethylenically unsaturated monomer component in an amount of no greater than 30 wt-%, based on the weight of the monomer mixture.

In certain embodiments, the methods of the present invention further include combining the emulsion polymerized latex polymer with one or more crosslinkers,

fillers, catalysts, dyes, pigments, toners, extenders, lubricants, anticorrosion agents, flow control agents, thixotropic agents, dispersing agents, antioxidants, adhesion promoters, light stabilizers, organic solvents, surfactants or combinations thereof in the coating composition.

5 In certain embodiments, the acid-functional polymer has a number average molecular weight of 1500 to 50,000.

 In certain embodiments, the composition is substantially free of mobile BPA and aromatic glycidyl ether compounds. Preferably, the composition is substantially free of bound BPA and aromatic glycidyl ether compounds.

10 In certain embodiments, the acid- or anhydride-functional polymer includes an acid- or anhydride-functional acrylic polymer, acid- or anhydride-functional alkyd resin, acid- or anhydride-functional polyester resin, acid- or anhydride-functional polyurethane, or combinations thereof. Preferably, the acid- or anhydride-functional polymer includes an acid-functional acrylic polymer.

15 In certain embodiments, the amine is a tertiary amine. Preferably, the tertiary amine is selected from the group consisting of trimethyl amine, dimethylethanol amine (also known as dimethylamino ethanol), methyldiethanol amine, triethanol amine, ethyl methyl ethanol amine, dimethyl ethyl amine, dimethyl propyl amine, dimethyl 3-hydroxy-1-propyl amine, dimethylbenzyl amine, dimethyl 20 2-hydroxy-1-propyl amine, diethyl methyl amine, dimethyl 1-hydroxy-2-propyl amine, triethyl amine, tributyl amine, N-methyl morpholine, and mixtures thereof. Preferably, the acid- or anhydride-functional polymer is at least 25% neutralized with the amine in water.

 In certain embodiments, the ethylenically unsaturated monomer component 25 is polymerized in the presence of the aqueous dispersion with a water-soluble free radical initiator at a temperature of 0°C to 100°C. In certain embodiments, the free radical initiator includes a peroxide initiator. Preferably, the free radical initiator includes hydrogen peroxide and benzoin. Alternatively, in certain embodiments the free radical initiator includes a redox initiator system.

30 The present invention also provides food cans and beverage cans prepared by a method described herein.

 In one embodiment, the present invention provides a food or beverage can that includes: a body portion or an end portion including a metal substrate; and a

coating composition disposed thereon, wherein the coating composition includes an emulsion polymerized latex polymer, wherein the emulsion polymerized latex polymer is prepared from a salt of an acid- or anhydride-functional polymer and an amine, an ethylenically unsaturated monomer component, and water.

5 In yet another embodiment, the present invention provides a composition for use in coating a food or beverage can, wherein the composition includes an emulsion polymerized latex polymer, wherein the emulsion polymerized latex polymer is prepared from a salt of an acid- or anhydride-functional polymer and an amine, an ethylenically unsaturated monomer component, and water.

10

Definitions

The term "substantially free" of a particular mobile compound means that the compositions of the present invention contain less than 1000 parts per million (ppm) of the recited mobile compound. The term "essentially free" of a particular mobile
15 compound means that the compositions of the present invention contain less than 100 parts per million (ppm) of the recited mobile compound. The term "essentially completely free" of a particular mobile compound means that the compositions of the present invention contain less than 5 parts per million (ppm) of the recited mobile compound. The term "completely free" of a particular mobile compound
20 means that the compositions of the present invention contain less than 20 parts per billion (ppb) of the recited mobile compound.

The term "mobile" means that the compound can be extracted from the cured coating when a coating (typically, approximate film weight of 1 mg/cm^2) is exposed to a test medium for some defined set of conditions, depending on the end use. An
25 example of these testing conditions is exposure of the cured coating to 10 weight percent ethanol solution for two hours at 121°C followed by exposure for 10 days in the solution at 49°C .

If the aforementioned phrases are used without the term "mobile" (e.g., "substantially free of XYZ compound") then the compositions of the present
30 invention contain less than the aforementioned amount of the compound whether the compound is mobile in the coating or bound to a constituent of the coating.

The terms "comprises" and variations thereof do not have a limiting meaning where these terms appear in the description and claims.

As used herein, "a," "an," "the," "at least one," and "one or more" are used interchangeably. Thus, for example, a coating composition that comprises "an"
5 amine can be interpreted to mean that the coating composition includes "one or more" amines.

Also herein, the recitations of numerical ranges by endpoints include all numbers subsumed within that range (e.g., 1 to 5 includes 1, 1.5, 2, 2.75, 3, 3.80, 4, 5, etc.).

10 The above summary of the present invention is not intended to describe each disclosed embodiment or every implementation of the present invention. The description that follows more particularly exemplifies illustrative embodiments. In several places throughout the application, guidance is provided through lists of examples, which examples can be used in various combinations. In each instance,
15 the recited list serves only as a representative group and should not be interpreted as an exclusive list.

Detailed Description of Illustrative Embodiments

This invention provides a coating composition for use on food and beverage
20 cans that includes a latex polymer. The polymer is prepared in an emulsion polymerization process, preferably a free radical initiated polymerization process. The latex polymer can be applied to a metal substrate either before or after the substrate is formed into a food or beverage can (e.g., two-piece cans, three-piece cans) or portions thereof, whether it be a can end or can body. The latex polymers
25 of the present invention are suitable for use in food contact situations and may be used on the inside of such cans. They are particularly useful on the interior of two-piece drawn and ironed beverage cans and on beverage can ends.

The latex polymer is prepared by polymerizing an ethylenically unsaturated monomer component in an aqueous medium in the presence of the salt of an acid
30 group- or anhydride group-containing polymer and an amine, preferably, a tertiary amine. The ethylenically unsaturated monomer component is preferably a mixture of monomers. Preferably, at least one of the monomers in the mixture is an alpha, beta-ethylenically unsaturated monomer, and preferably at least one of the

monomers contains an oxirane groups. More preferably, at least one of the monomers is an oxirane group-containing alpha, beta-ethylenically unsaturated monomer.

5 The composition may optionally include crosslinkers, fillers, catalysts, dyes, pigments, toners, extenders, lubricants, anticorrosion agents, flow control agents, thixotropic agents, dispersing agents, antioxidants, adhesion promoters, light stabilizers, surfactants, organic solvents, and mixtures thereof as required to provide the desired film properties.

10 In one embodiment, the coating composition is prepared by: forming a salt of an acid-functional or anhydride-functional polymer and an amine; dispersing the salt in a carrier that includes water and an optional organic solvent to form an aqueous dispersion; optionally removing the organic solvent, if present, from the aqueous dispersion; combining an ethylenically unsaturated monomer component with the aqueous dispersion (preferably, the ethylenically unsaturated monomer component is added to the aqueous dispersion); and polymerizing the ethylenically
15 unsaturated monomer component in the presence of the aqueous dispersion to form an emulsion polymerized latex polymer.

Preferred compositions and dispersions are substantially free of mobile bisphenol A (BPA) and aromatic glycidyl ether compounds (e.g., BADGE, BFDGE, and epoxy novalacs), more preferably essentially free of these compounds, even
20 more preferably essentially completely free of these compounds, and most preferably completely free of these compounds. The coating composition is also preferably substantially free of bound BPA and aromatic glycidyl ether compounds, more preferably essentially free of these compounds, most preferably essentially completely free of these compounds, and optimally completely free of these
25 compounds.

The ethylenically unsaturated monomer component is preferably a mixture of monomers that is capable of free radical initiated polymerization in aqueous medium. The monomer mixture preferably contains at least one oxirane functional
30 monomer, and more preferably, at least one oxirane group-containing alpha, beta-ethylenically unsaturated monomer.

The monomer mixture preferably contains at least 0.1 percent by weight (wt-%), more preferably at least 1 wt-%, of an oxirane group-containing monomer,

based on the weight of the monomer mixture. Typically, at least 0.1 wt-% of the oxirane group-containing monomer contributes to the stability of the latex.

Although not intended to be limited by theory, it is believed that this is because of the reduction in the amount of quaternary salt formation between the oxirane species, acid group-containing polymer, and amine, which can cause coagulation of the latex. In addition, at least 0.1 wt-% of the oxirane group-containing monomer contributes to crosslinking in the dispersed particles and during cure, resulting in better properties of coating compositions formulated with the polymeric latices.

The monomer mixture preferably contains no greater than 30 wt-%, more preferably no greater than 20 wt-%, even more preferably no greater than 10 wt-%, and optimally no greater than 9 wt-%, of the oxirane group-containing monomer, based on the weight of the monomer mixture. Typically, greater than 30 wt-% of the oxirane group-containing monomer in the monomer mixture can contribute to diminished film properties. Although not intended to be limited by theory, it is believed that this is due to embrittlement caused by an overabundance of crosslinking.

Suitable oxirane-functional monomers include monomers having a reactive carbon-carbon double bond and an oxirane (i.e., a glycidyl) group. Typically, the monomer is a glycidyl ester of an alpha, beta-unsaturated acid, or anhydride thereof (i.e., an oxirane group-containing alpha, beta-ethylenically unsaturated monomer). Suitable alpha, beta-unsaturated acids include monocarboxylic acids or dicarboxylic acids. Examples of such carboxylic acids include, but are not limited to, acrylic acid, methacrylic acid, alpha-chloroacrylic acid, alpha-cyanoacrylic acid, beta-methylacrylic acid (crotonic acid), alpha-phenylacrylic acid, beta-acryloxypropionic acid, sorbic acid, alpha-chlorosorbic acid, angelic acid, cinnamic acid, p-chlorocinnamic acid, beta-stearylacrylic acid, itaconic acid, citraconic acid, mesaconic acid, glutaconic acid, aconitic acid, maleic acid, fumaric acid, tricarboxyethylene, maleic anhydride, and mixtures thereof.

Specific examples of suitable monomers containing a glycidyl group are glycidyl (meth)acrylate (i.e., glycidyl methacrylate and glycidyl acrylate), mono- and di-glycidyl itaconate, mono- and di-glycidyl maleate, and mono- and di-glycidyl formate. It also is envisioned that allyl glycidyl ether and vinyl glycidyl ether can be

used as the oxirane-functional monomer. A preferred monomer is glycidyl methacrylate ("GMA").

The oxirane-functional monomer is preferably reacted with suitable other monomers within the monomer mixture. These can be ethylenically unsaturated monomer and hydroxy-functional monomers. Suitable ethylenically unsaturated monomers include alkyl (meth)acrylates, vinyl monomers, alkyl esters of maleic or fumaric acid, and the like.

Suitable alkyl (meth)acrylates include those having the structure: $\text{CH}_2=\text{C}(\text{R}^1)-\text{CO}-\text{OR}^2$ wherein R^1 is hydrogen or methyl, and R^2 is an alkyl group preferably containing one to sixteen carbon atoms. The R^2 group can be substituted with one or more, and typically one to three, moieties such as hydroxy, halo, phenyl, and alkoxy, for example. Suitable alkyl (meth)acrylates therefore encompass hydroxy alkyl (meth)acrylates. The alkyl (meth)acrylate typically is an ester of acrylic or methacrylic acid. Preferably, R^1 is hydrogen or methyl and R^2 is an alkyl group having two to eight carbon atoms. Most preferably, R^1 is hydrogen or methyl and R^2 is an alkyl group having two to four carbon atoms.

Examples of suitable alkyl (meth)acrylates include, but are not limited to, methyl (meth)acrylate, ethyl (meth)acrylate, propyl (meth)acrylate, isopropyl (meth)acrylate, butyl (meth)acrylate, isobutyl (meth)acrylate, pentyl (meth)acrylate, isoamyl (meth)acrylate, hexyl (meth)acrylate, 2-ethylhexyl (meth)acrylate, cyclohexyl (meth)acrylate, decyl (meth)acrylate, isodecyl (meth)acrylate, benzyl (meth)acrylate, lauryl (meth)acrylate, isobornyl (meth)acrylate, octyl (meth)acrylate, nonyl (meth)acrylate, hydroxyethyl acrylate (HEA), hydroxyethyl methacrylate (HEMA), hydroxypropyl (meth)acrylate (HPMA).

Difunctional (meth)acrylate monomers may be used in the monomer mixture as well. Examples include ethylene glycol di(meth)acrylate, 1,6-hexanediol di(meth)acrylate, allyl methacrylate, and the like.

Suitable vinyl monomers include styrene, methyl styrene, halostyrene, isoprene, diallylphthalate, divinylbenzene, conjugated butadiene, alpha-methylstyrene, vinyl toluene, vinyl naphthalene, and mixtures thereof. The vinyl aromatic monomers described below in connection with the acid- or anhydride-functional polymer are also suitable for use in the ethylenically unsaturated

monomer component used to make the latex polymer. Styrene is a presently preferred vinyl monomer, in part due to its relatively low cost.

Other suitable polymerizable vinyl monomers for use in the ethylenically unsaturated monomer component include acrylonitrile, acrylamide, methacrylamide, methacrylonitrile, vinyl acetate, vinyl propionate, vinyl butyrate, vinyl stearate, N-isobutoxymethyl acrylamide, N-butoxymethyl acrylamide, and the like.

The oxirane group-containing monomer preferably constitutes 0.1 wt-% to 30 wt-%, and more preferably 1 wt-% to 20 wt-%, of the ethylenically unsaturated monomer component. The other monomer or monomers in the mixture constitute the remainder of the monomer component, that is, 70 wt-% to 99.9 wt-%, preferably 80 wt-% to 99 wt-%, based on total weight of the monomer mixture.

Preferably, at least 40 wt-% of the ethylenically unsaturated monomer component, more preferably at least 50 wt-%, will be selected from alkyl acrylates and methacrylates. Preferably, at least 20 wt-%, more preferably at least 30 wt-%, will be selected from vinyl aromatic compounds.

Preferably, at least 5 wt-%, more preferably at least 25 wt-%, even more preferably at least 50 wt-%, and even more preferably at least 60 wt-%, of the ethylenically unsaturated monomer component is used in making the latex polymer. Preferably, no greater than 95 wt-%, more preferably no greater than 90 wt-%, and even more preferably no greater than 85 wt-%, of the ethylenically unsaturated monomer component is used in making the latex polymer. Such percentages are based on total weight of ethylenically unsaturated monomer component and salt of the acid group-containing or anhydride group-containing polymer (i.e., acid-functional or anhydride-functional polymer).

Among the acid functional polymers that can be employed in preparing the latex polymer of the present invention are virtually any acid-containing or anhydride-containing polymers that can be neutralized or partially neutralized with an appropriate amine to form a salt that can be dissolved or stably dispersed in the aqueous medium. The choice of the acid-containing or anhydride-containing monomer(s) is dictated by the intended end use of the coating composition and is practically unlimited.

The acid-containing polymer (i.e., acid-functional polymer) preferably has an acid number of at least 40, and more preferably at least 100, milligrams (mg) KOH

per gram resin. The acid-containing polymer preferably has an acid number of no greater than 400, and more preferably no greater than 300, mg KOH per gram resin. The anhydride-containing polymer, when in water, preferably has similar acid number ranges.

5 Low molecular weight polymers are preferred for certain applications of the present invention. Preferably, the molecular weight of the acid- or anhydride-functional polymer is no greater than 50,000 on a number average molecular weight basis, and preferably no greater than 20,000. Preferably, the molecular weight of the acid- or anhydride-functional polymer is at least 1500 on a number average
10 molecular weight basis, and more preferably at least 2000.

 Preferred acid- or anhydride-functional polymers that may be employed include acid-functional or anhydride-functional acrylic polymers, alkyd resins, polyester polymers, and polyurethanes. Combinations of such polymers can be used if desired. Herein, the term polymer includes both homopolymers and copolymers
15 (i.e., polymers of two or more different monomers).

 Preferred acid- or anhydride-functional polymers utilized in this invention include those prepared by conventional free radical polymerization techniques. Suitable examples include those prepared from unsaturated acid- or anhydride-functional monomers, or salts thereof, and other unsaturated monomers. Of these,
20 preferred examples include those prepared from at least 15 wt-%, more preferably at least 20 wt-%, unsaturated acid- or anhydride-functional monomer, or salts thereof, and the balance other polymerizable unsaturated monomer. Examples of comonomers described previously apply here as well.

 A variety of acid- or anhydride-functional monomers, or salts thereof, can be
25 used; their selection is dependent on the desired final polymer properties. Preferably, such monomers are ethylenically unsaturated, more preferably, alpha, beta-ethylenically unsaturated. Suitable ethylenically unsaturated acid- or anhydride-functional monomers for the present invention include monomers having a reactive carbon-carbon double bond and an acidic or anhydride group, or salts
30 thereof. Preferred such monomers have from 3 to 20 carbons, at least 1 site of unsaturation, and at least 1 acid or anhydride group, or salt thereof.

 Suitable acid-functional monomers include ethylenically unsaturated acids (mono-protic or diprotic), anhydrides or monoesters of a dibasic acid, which are

copolymerizable with the optional other monomer(s) used to prepare the polymer. Illustrative monobasic acids are those represented by the structure $\text{CH}_2=\text{C}(\text{R}^3)\text{-COOH}$, where R^3 is hydrogen or an alkyl radical of 1 to 6 carbon atoms. Suitable dibasic acids are those represented by the formulas $\text{R}^4(\text{COOH})\text{C}=\text{C}(\text{COOH})\text{R}^5$ and $\text{R}^4(\text{R}^5)\text{C}=\text{C}(\text{COOH})\text{R}^6\text{COOH}$, where R^4 and R^5 are hydrogen, an alkyl radical of 1-8 carbon atoms, halogen, cycloalkyl of 3 to 7 carbon atoms or phenyl, and R^6 is an alkylene radical of 1 to 6 carbon atoms. Half-esters of these acids with alkanols of 1 to 8 carbon atoms are also suitable.

Non-limiting examples of useful ethylenically unsaturated acid-functional monomers include acids such as, for example, acrylic acid, methacrylic acid, alpha-chloroacrylic acid, alpha-cyanoacrylic acid, crotonic acid, alpha-phenylacrylic acid, beta-acryloxypropionic acid, fumaric acid, maleic acid, sorbic acid, alpha-chlorosorbic acid, angelic acid, cinnamic acid, p-chlorocinnamic acid, beta-stearylacrylic acid, citraconic acid, mesaconic acid, glutaconic acid, aconitic acid, tricarboxyethylene, 2-methyl maleic acid, itaconic acid, 2-methyl itaconic acid, methyleneglutaric acid, and the like, or mixtures thereof. Preferred unsaturated acid-functional monomers include acrylic acid, methacrylic acid, crotonic acid, fumaric acid, maleic acid, 2-methyl maleic acid, itaconic acid, 2-methyl itaconic acid and mixtures thereof. More preferred unsaturated acid-functional monomers include acrylic acid, methacrylic acid, crotonic acid, fumaric acid, maleic acid, itaconic acid, and mixtures thereof. Most preferred unsaturated acid-functional monomers include acrylic acid, methacrylic acid, maleic acid, crotonic acid, and mixtures thereof.

Nonlimiting examples of suitable ethylenically unsaturated anhydride monomers include compounds derived from the above acids (e.g., as pure anhydride or mixtures of such). Preferred anhydrides include acrylic anhydride, methacrylic anhydride, and maleic anhydride. If desired, aqueous salts of the above acids may also be employed.

Polymerization of the monomers to form an acid- or anhydride-functional polymer is usually conducted by organic solution polymerization techniques in the presence of a free radical initiator as is well known in the art. Although the preparation of the acid-functional or anhydride-functional polymer is conveniently carried out in solution, neat processes may be used if desired.

Besides the acid- or anhydride-functional acrylic polymers, acid- or anhydride-functional alkyd, polyester, polyurethane resins, or combinations thereof, can also be used in the practice of the invention. Such polymers are described in U.S. Pat. Nos. 4,692,491; 3,479,310; and 4,147,679. Preferably, the acid- or anhydride-functional polymers are acid-functional acrylic polymers.

A salt (which can be a full salt or partial salt) of the acid- or anhydride-functional polymer is formed by neutralizing or partially neutralizing the acid groups (whether present initially in the acid-functional polymer or formed upon addition of the anhydride-functional polymer to water) of the polymer with a suitable amine, preferably a tertiary amine. The degree of neutralization required to form the desired polymer salt may vary considerably depending upon the amount of acid included in the polymer, and the degree of solubility or dispersibility of the salt which is desired. Ordinarily in making the polymer water-dispersible, the acidity of the polymer is at least 25% neutralized, preferably at least 30% neutralized, and more preferably at least 35% neutralized, with the amine in water.

Some examples of suitable tertiary amines are trimethyl amine, dimethylethanol amine (also known as dimethylamino ethanol), methyldiethanol amine, triethanol amine, ethyl methyl ethanol amine, dimethyl ethyl amine, dimethyl propyl amine, dimethyl 3-hydroxy-1-propyl amine, dimethylbenzyl amine, dimethyl 2-hydroxy-1-propyl amine, diethyl methyl amine, dimethyl 1-hydroxy-2-propyl amine, triethyl amine, tributyl amine, N-methyl morpholine, and mixtures thereof. Most preferably triethyl amine or dimethyl ethanol amine is used as the tertiary amine.

The amount of the salt of the acid-functional or anhydride-functional polymer that is used in the polymerization is preferably at least 5 wt-%, more preferably at least 10 wt-%, and even more preferably at least 15 wt-%. The amount of the salt of the acid-functional or anhydride-functional polymer that is used in the polymerization is preferably no greater than 95 wt-%, preferably no greater than 50 wt-%, and even more preferably no greater than 40 wt-%. These percentages are based on total weight of polymerizable ethylenically unsaturated monomer component and the salt of the acid group-containing polymer.

The reaction of tertiary amines with materials containing oxirane groups, when carried out in the presence of water, can afford a product that contains both a

hydroxyl group and a quaternary ammonium hydroxide. Under preferred conditions an acid group, an oxirane group, and an amine form a quaternary salt. This linkage is favored, as it not only links the polymers but promotes water dispersibility of the joined polymer. It should be noted that an acid group and an oxirane group may also
5 form an ester. Some of this reaction is possible, though this linkage is less desirable when water dispersibility is sought.

While the exact mode of reaction is not fully understood, it is believed that a competition between the two reactions exist; however, this is not intended to be limiting. In preferred embodiments, one reaction involves the tertiary amine
10 neutralized acid-functional polymer reacting with an oxirane-functional monomer or polymer to form a quaternary ammonium salt. A second reaction involves esterification of the oxirane-functional monomer or polymer with a carboxylic acid or salt. In the current invention it is believed the presence of water and level of amine favor formation of quaternary ammonium salts over ester linkages. A high
15 level of quaternization improves water dispersability while a high level of esterification gives higher viscosity and possibly gel-like material.

With regard to the conditions of the emulsion polymerization, the ethylenically unsaturated monomer component is preferably polymerized in aqueous medium with a water-soluble free radical initiator in the presence of the salt of the
20 acid- or anhydride-functional polymer.

The temperature of polymerization is typically from 0°C to 100°C, preferably from 50°C to 90°C, more preferably from 70°C to 90°C, and even more preferably from 80°C to 85°C. The pH of the aqueous medium is usually maintained at a pH of 5 to 12.

25 The free radical initiator can be selected from one or more water-soluble peroxides which are known to act as free radical initiators. Examples include hydrogen peroxide and t-butyl hydroperoxide. Redox initiator systems well known in the art (e.g., t-butyl hydroperoxide, erythorbic acid, and ferrous complexes) can also be employed. It is especially preferred to use a mixture of benzoin and
30 hydrogen peroxide. Persulfate initiators such as ammonium persulfate or potassium persulfate are not preferred, as they lead to poor water resistance properties of the cured coating.

The polymerization reaction of the ethylenically unsaturated monomer component in the presence of the aqueous dispersion of the polymer salt may be conducted as a batch, intermittent, or continuous operation. While all of the polymerization ingredients may be charged initially to the polymerization vessel,
5 better results normally are obtained with proportioning techniques.

Typically, the reactor is charged with an appropriate amount of water, polymer salt, and free radical initiator. The reactor is then heated to the free radical initiation temperature and then charged with the ethylenically unsaturated monomer component. Preferably only water, initiator, polymer salt, and some portion of the
10 ethylenically unsaturated monomer component are initially charged to the vessel. There may also be some water miscible solvent present. After this initial charge is allowed to react for a period of time at polymerization temperature, the remaining ethylenically unsaturated monomer component is added incrementally with the rate of addition being varied depending on the polymerization temperature, the particular
15 initiator being employed, and the type and amount of monomers being polymerized. After all the monomer component has been charged, a final heating is carried out to complete the polymerization. The reactor is then cooled and the latex recovered.

It has been discovered that coating compositions using the aforementioned latices may be formulated using one or more optional curing agents (i.e.,
20 crosslinking resins, sometimes referred to as "crosslinkers"). The choice of particular crosslinker typically depends on the particular product being formulated. For example, some coating compositions are highly colored (e.g., gold-colored coatings). These coatings may typically be formulated using crosslinkers that themselves tend to have a yellowish color. In contrast, white coatings are generally
25 formulated using non-yellowing crosslinkers, or only a small amount of a yellowing crosslinker. Preferred curing agents are substantially free of mobile BPA and aromatic glycidyl ether compounds (e.g., BADGE, BFDGE and epoxy novalacs).

Any of the well known hydroxyl-reactive curing resins can be used. For example, phenoplast, and aminoplast curing agents may be used.

30 Phenoplast resins include the condensation products of aldehydes with phenols. Formaldehyde and acetaldehyde are preferred aldehydes. Various phenols can be employed such as phenol, cresol, p-phenylphenol, p-tert-butylphenol, p-tert-amylphenol, and cyclopentylphenol.

Aminoplast resins are the condensation products of aldehydes such as formaldehyde, acetaldehyde, crotonaldehyde, and benzaldehyde with amino or amido group-containing substances such as urea, melamine and benzoguanamine.

5 Examples of suitable crosslinking resins include, without limitation, benzoguanamine-formaldehyde resins, melamine-formaldehyde resins, esterified melamine-formaldehyde, and urea-formaldehyde resins. Preferably, the crosslinker employed when practicing this invention includes a melamine-formaldehyde resin. One specific example of a particularly useful crosslinker is the fully alkylated melamine-formaldehyde resin commercially available from Cytac Industries, Inc.
10 under the trade name of CYMEL 303.

As examples of other generally suitable curing agents are the blocked or non-blocked aliphatic, cycloaliphatic or aromatic di-, tri-, or poly-valent isocyanates, such as hexamethylene diisocyanate, cyclohexyl-1,4-diisocyanate, and the like.

The level of curing agent (i.e., crosslinker) required will depend on the type
15 of curing agent, the time and temperature of the bake, and the molecular weight of the polymer. If used, the crosslinker is typically present in an amount of up to 50 wt-%, preferably up to 30 wt-%, and more preferably up to 15 wt-%. These weight percentages are based upon the total weight of the resin solids in the coating composition.

20 A coating composition of the present invention may also include other optional polymers that do not adversely affect the coating composition or a cured coating composition resulting therefrom. Such optional polymers are typically included in a coating composition as a filler material, although they can be included as a crosslinking material, or to provide desirable properties. One or more optional
25 polymers (e.g., filler polymers) can be included in a sufficient amount to serve an intended purpose, but not in such an amount to adversely affect a coating composition or a cured coating composition resulting therefrom.

Such additional polymeric materials can be nonreactive, and hence, simply function as fillers. Such optional nonreactive filler polymers include, for example,
30 polyesters, acrylics, polyamides, polyethers, and polyurethanes. Alternatively, such additional polymeric materials or monomers can be reactive with other components of the composition (e.g., the acid-functional polymer). If desired, reactive polymers can be incorporated into the compositions of the present invention, to provide

additional functionality for various purposes, including crosslinking. Examples of such reactive polymers include, for example, functionalized polyesters, acrylics, polyamides, and polyethers. Preferred optional polymers are substantially free of mobile BPA and aromatic glycidyl ether compounds (e.g., BADGE, BFDGE and epoxy novalacs)

A coating composition of the present invention may also include other optional ingredients that do not adversely affect the coating composition or a cured coating composition resulting therefrom. Such optional ingredients are typically included in a coating composition to enhance composition esthetics, to facilitate manufacturing, processing, handling, and application of the composition, and to further improve a particular functional property of a coating composition or a cured coating composition resulting therefrom.

Such optional ingredients include, for example, catalysts, dyes, pigments, toners, extenders, fillers, lubricants, anticorrosion agents, flow control agents, thixotropic agents, dispersing agents, antioxidants, adhesion promoters, light stabilizers, surfactants, and mixtures thereof. Each optional ingredient is included in a sufficient amount to serve its intended purpose, but not in such an amount to adversely affect a coating composition or a cured coating composition resulting therefrom.

One preferred optional ingredient is a catalyst to increase the rate of cure. Examples of catalysts, include, but are not limited to, strong acids (e.g., dodecylbenzene sulphonic acid (DDBSA, available as CYCAT 600 from Cytec), methane sulfonic acid (MSA), p-toluene sulfonic acid (pTSA), dinonylnaphthalene disulfonic acid (DNNDSA), and triflic acid), quaternary ammonium compounds, phosphorous compounds, and tin and zinc compounds. Specific examples include, but are not limited to, a tetraalkyl ammonium halide, a tetraalkyl or tetraaryl phosphonium iodide or acetate, tin octoate, zinc octoate, triphenylphosphine, and similar catalysts known to persons skilled in the art. If used, a catalyst is preferably present in an amount of at least 0.01 wt-%, and more preferably at least 0.1 wt-%, based on the weight of nonvolatile material. If used, a catalyst is preferably present in an amount of no greater than 3 wt-%, and more preferably no greater than 1 wt-%, based on the weight of nonvolatile material.

Another useful optional ingredient is a lubricant (e.g., a wax), which facilitates manufacture of metal closures by imparting lubricity to sheets of coated metal substrate. Preferred lubricants include, for example, Carnauba wax and polyethylene type lubricants. If used, a lubricant is preferably present in the coating composition in an amount of at least 0.1 wt-%, and preferably no greater than 2 wt-%, and more preferably no greater than 1 wt-%, based on the weight of nonvolatile material.

Another useful optional ingredient is a pigment, such as titanium dioxide. If used, a pigment is present in the coating composition in an amount of no greater than 70 wt-%, more preferably no greater than 50 wt-%, and even more preferably, no greater than 40 wt-%, based on the total weight of solids in the coating composition.

Surfactants can be optionally added to the coating composition to aid in flow and wetting of the substrate. Examples of surfactants, include, but are not limited to, nonylphenol polyethers and salts and similar surfactants known to persons skilled in the art. If used, a surfactant is preferably present in an amount of at least 0.01 wt-%, and more preferably at least 0.1 wt-%, based on the weight of resin solids. If used, a surfactant is preferably present in an amount no greater than 10 wt-%, and more preferably no greater than 5 wt-%, based on the weight of resin solids.

As described above, the coating compositions of the present invention are particularly well adapted for use on food and beverage cans (e.g., two-piece cans, three-piece cans, etc.). Two-piece cans are manufactured by joining a can body (typically a drawn metal body) with a can end (typically a drawn metal end). The coatings of the present invention are suitable for use in food or beverage contact situations and may be used on the inside of such cans. They are particularly suitable for spray applied, liquid coatings for the interior of two-piece drawn and ironed beverage cans and coil coatings for beverage can ends. The present invention also offers utility in other applications. These additional applications include, but are not limited to, wash coating, sheet coating, and side seam coatings (e.g., food can side seam coatings).

Spray coating includes the introduction of the coated composition into the inside of a preformed packaging container. Typical preformed packaging containers suitable for spray coating include food cans, beer and beverage containers, and the

like. The spray preferably utilizes a spray nozzle capable of uniformly coating the inside of the preformed packaging container. The sprayed preformed container is then subjected to heat to remove the residual solvents and harden the coating.

5 A coil coating is described as the coating of a continuous coil composed of a metal (e.g., steel or aluminum). Once coated, the coating coil is subjected to a short thermal, ultraviolet, and/or electromagnetic curing cycle, for hardening (e.g., drying and curing) of the coating. Coil coatings provide coated metal (e.g., steel and/or aluminum) substrates that can be fabricated into formed articles, such as 2-piece drawn food cans, 3-piece food cans, food can ends, drawn and ironed cans, beverage
10 can ends, and the like.

A wash coating is commercially described as the coating of the exterior of two-piece drawn and ironed ("D&I") cans with a thin layer of protectant coating. The exterior of these D&I cans are "wash-coated" by passing pre-formed two-piece D&I cans under a curtain of a coating composition. The cans are inverted, that is, the
15 open end of the can is in the "down" position when passing through the curtain. This curtain of coating composition takes on a "waterfall-like" appearance. Once these cans pass under this curtain of coating composition, the liquid coating material effectively coats the exterior of each can. Excess coating is removed through the use of an "air knife." Once the desired amount of coating is applied to the exterior of
20 each can, each can is passed through a thermal, ultraviolet, and/or electromagnetic curing oven to harden (e.g., dry and cure) the coating. The residence time of the coated can within the confines of the curing oven is typically from 1 minute to 5 minutes. The curing temperature within this oven will typically range from 150°C to 220°C.

25 A sheet coating is described as the coating of separate pieces of a variety of materials (e.g., steel or aluminum) that have been pre-cut into square or rectangular "sheets." Typical dimensions of these sheets are approximately one square meter. Once coated, each sheet is cured. Once hardened (e.g., dried and cured), the sheets of the coated substrate are collected and prepared for subsequent fabrication. Sheet
30 coatings provide coated metal (e.g., steel or aluminum) substrate that can be successfully fabricated into formed articles, such as 2-piece drawn food cans, 3-piece food cans, food can ends, drawn and ironed cans, beverage can ends, and the like.

A side seam coating is described as the spray application of a liquid coating over the welded area of formed three-piece food cans. When three-piece food cans are being prepared, a rectangular piece of coated substrate is formed into a cylinder. The formation of the cylinder is rendered permanent due to the welding of each side of the rectangle via thermal welding. Once welded, each can typically requires a layer of liquid coating, which protects the exposed "weld" from subsequent corrosion or other effects to the contained foodstuff. The liquid coatings that function in this role are termed "side seam stripes." Typical side seam stripes are spray applied and cured quickly via residual heat from the welding operation in addition to a small thermal, ultraviolet, and/or electromagnetic oven.

Other commercial coating application and curing methods are also envisioned, for example, electrocoating, extrusion coating, laminating, powder coating, and the like.

Preferred coatings of the present invention display one or more of the properties described in the Examples Section. More preferred coatings of the present invention display one or more of the following properties: metal exposure value of less than 3 mA; metal exposure value after drop damage of less than 3.5 mA; global extraction results of less than 50 ppm; adhesion rating of 10; blush rating of at least 7; slight or no crazing in a reverse impact test; no craze (rating of 10) in a dome impact test; feathering below 0.2 inch; COF range of 0.055 to 0.095; and after pasteurization or retort, a continuity of less than 20 mA.

EXAMPLES

The following examples are offered to aid in understanding of the present invention and are not to be construed as limiting the scope thereof. Unless otherwise indicated, all parts and percentages are by weight. The constructions cited were evaluated by tests as follows:

Initial Metal Exposure

This test method determines the amount the inside surface of the can that has not been effectively coated by the sprayed coating. This determination is made thorough the use of an electrically conductive solution (1% NaCl in deionized water). The coated can is filled with this conductive solution, and an electrical

probe is attached in contact to the outside of the can (uncoated, electrically conducting). A second probe is immersed in the salt solution in the middle of the inside of the can. If any uncoated metal is present on the inside of the can, a current is passed between these two probes and registers as a value on an LED display. The LED displays the conveyed currents in milliamps (mA). The current that is passed is directly proportional to the amount of metal that has not been effectively covered with coating. The goal is to achieve 100% coating coverage on the inside of the can, which would result in an LED reading of 0.0 mA. Preferred coatings give metal exposure values of less than 3 mA, more preferred values of less than 2 mA, and even more preferred values of less than 1 mA. Commercially acceptable metal exposure values are typically less than 2.0 mA on average.

Metal Exposure After Drop Damage

Drop damage resistance measures the ability of the coated container to resist cracks after being conditions simulating dropping of a filled can. The presence of cracks is measured by passing electrical current via an electrolyte solution, as previously described in the Metal Exposure section. A coated container is filled with the electrolyte solution and the initial metal exposure is recorded. The can is then filled with water and dropped through a tube from a specified height onto an inclined plane, causing a dent in the chime area. The can is then turned 180 degrees, and the process is repeated. Water is then removed from the can and metal exposure is again measured as described above. If there is no damage, no change in current (mA) will be observed. Typically, an average of 6 or 12 container runs is recorded. Both metal exposures results before and after the drop are reported. The lower the milliamp value, the better the resistance of the coating to drop damage. Preferred coatings give metal exposure values after drop damage of less than 3.5 mA, more preferred valued of less than 2.5 mA, and even more preferred values of less than 1.5 mA.

Solvent Resistance

The extent of "cure" or crosslinking of a coating is measured as a resistance to solvents, such as methyl ethyl ketone (MEK) or isopropyl alcohol (IPA). This

test is performed as described in ASTM D 5402 – 93. The number of double-rubs (i.e., one back-and forth motion) is reported.

Global Extractions

5 The global extraction test is designed to estimate the total amount of mobile material that can potentially migrate out of a coating and into food packed in a coated can. Typically coated substrate is subjected to water or solvent blends under a variety of conditions to simulate a given end-use. Acceptable extraction conditions and media can be found in 21CFR 175.300 paragraphs (d) and (e). The allowable
10 global extraction limit as defined by the FDA regulation is 50 parts per million (ppm).

 The extraction procedure used in the current invention is described in 21CFR 175.300 paragraph (e) (4) (xv) with the following modifications to ensure worst-case scenario performance: 1) the alcohol content was increased to 10% by weight and 2)
15 the filled containers were held for a 10-day equilibrium period at 100°F. These conditions are per the FDA publication "Guidelines for Industry" for preparation of Food Contact Notifications. The coated beverage can was filled with 10 weight percent aqueous ethanol and subjected to pasteurization conditions (150°F) for 2 hours, followed by a 10-day equilibrium period at 100°F. Determination of the
20 amount of extractives was determined as described in 21CFR 175.300 paragraph (e) (5), and ppm values were calculated based on surface area of the can (no end) of 44 square inches with a volume of 355 ml. Preferred coatings give global extraction results of less than 50 ppm, more preferred results of less than 10 ppm, even more preferred results of less than 1 ppm. Most preferably, the global extraction results
25 are optimally non-detectable.

Adhesion

 Adhesion testing is performed to assess whether the coating adheres to the coated substrate. The adhesion test was performed according to ASTM D 3359 –
30 Test Method B, using SCOTCH 610 tape, available from 3M Company of Saint Paul, Minnesota. Adhesion is generally rated on a scale of 0-10 where a rating of "10" indicates no adhesion failure, a rating of "9" indicates 90% of the coating remains adhered, a rating of "8" indicates 80% of the coating remains adhered, and

so on. Adhesion ratings of 10 are typically desired for commercially viable coatings.

Blush Resistance

5 Blush resistance measures the ability of a coating to resist attack by various solutions. Typically, blush is measured by the amount of water absorbed into a coated film. When the film absorbs water, it generally becomes cloudy or looks white. Blush is generally measured visually using a scale of 0-10 where a rating of "10" indicates no blush and a rating of "0" indicates complete whitening of the film.
10 Blush ratings of at least 7 are typically desired for commercially viable coatings and optimally 9 or above.

Process or Retort Resistance

15 This is a measure of the coating integrity of the coated substrate after exposure to heat and pressure with a liquid such as water. Retort performance is not necessarily required for all food and beverage coatings, but is desirable for some product types that are packed under retort conditions. The procedure is similar to the Sterilization or Pasteurization test. Testing is accomplished by subjecting the substrate to heat ranging from 105-130°C and pressure ranging from 0.7 to 1.05
20 kg/cm² for a period of 15 to 90 minutes. For the present evaluation, the coated substrate was immersed in deionized water and subjected to heat of 121°C (250°F) and pressure of 1.05 kg/cm² for a period of 90 minutes. The coated substrate was then tested for adhesion and blush as described above. In food or beverage applications requiring retort performance, adhesion ratings of 10 and blush ratings of
25 at least 7 are typically desired for commercially viable coatings.

Crazing - Reverse Impact Resistance

30 The reverse impact measures the coated substrate's ability to withstand the deformation encountered when impacted by a steel punch with a hemispherical head. For the present evaluation, coated substrate was subjected to 12 in-lbs (1.36 N m) of force using BYK-Gardner "overall" Bend and Impact Tester and rated visually for micro-cracking or micro-fracturing – commonly referred to as crazing. Test pieces were impacted on the uncoated or reverse side. A rating of 10 indicates no

craze and suggests sufficient flexibility and cure. A rating of 0 indicates complete failure. Commercially viable coatings preferably show slight or no crazing on a reverse impact test.

5 **Impact on Dome**

Dome impact was evaluated by subjecting the dome apex of a 12 oz. beverage can to a reverse impact as described in the previous section. Craze was evaluated after impact. A rating of 10 indicates no craze and suggests sufficient flexibility and cure. A rating of 0 indicates complete failure. Coatings for beverage
10 can interiors preferably show no craze (rating of 10) on a dome impact.

Joy Detergent Test

A 1% solution of JOY Detergent (available from Procter & Gamble) in deionized water is prepared and heated to 82°C (180°F). Coated panels are
15 immersed in the heated solution for 10 minutes and are then removed, rinsed, and dried. Samples are then evaluated for adhesion and blush, as previously described. Commercially viable beverage interior coatings preferably give adhesion ratings of 10 and blush ratings of at least 7, optimally at least 9, in the detergent test.

20 **Feathering**

Feathering is a term used to describe the adhesion loss of a coating on the tab of a beverage can end. When a beverage can is opened, a portion of free film may be present across the opening of the can if the coating loses adhesion on the tab. This is feathering.

25 To test feathering, a "tab" is scored on the backside of a coated panel, with the coated side of the panel facing downward. The test piece is then pasteurized as described under the Pasteurization section below.

After pasteurization, pliers are used to bend the cut "tab" to a 90 degree angle away from the coated side of the substrate. The test piece is then placed on a flat
30 surface, coated side down. The cut "tab" is gripped using pliers and the "tab" is pulled from the test panel at an angle of 180 degrees until it is completely removed. After removing the "tab," any coating that extends into the opening on the test panel is measured. The distance of the greatest penetration (feathering) is reported in

inches. Coatings for beverage ends preferably show feathering below 0.2 inch, more preferably below 0.1 inch, most preferably below 0.05 inch, and optimally below 0.02 inch.

5 **Dowfax Detergent Test**

10 The "Dowfax" test is designed to measure the resistance of a coating to a boiling detergent solution. This is a general test run for beverage end coatings and is mainly used to evaluate adhesion. Historically, this test was used to indicate problems with the interaction of coating to substrate pretreatment. The solution is prepared by mixing 5 ml of Dowfax 2A1 (product of Dow Chemical) into 3000 ml of deionized water. Typically, coated substrate strips are immersed into the boiling Dowfax solution for 15 minutes. The strips are then rinsed and cooled in deionized water, dried, and then tested and rated for blush and adhesion as described previously. Preferred beverage end coatings provide adhesion ratings of 10 and
15 blush ratings of at least 4, more preferably 6 or above in the Dowfax detergent test.

Sterilization or Pasteurization

20 The sterilization or pasteurization test determines how a coating withstands the processing conditions for different types of food products packaged in a container. Typically, a coated substrate is immersed in a water bath and heated for 5-60 minutes at temperatures ranging from 65°C to 100°C. For the present evaluation, the coated substrate was immersed in a deionized water bath for 45 minutes at 85°C. The coated substrate was then removed from the water bath and tested for coating adhesion and blush as described above. Commercially viable
25 coatings preferably provide adequate pasteurization resistance with perfect adhesion (rating of 10) and blush ratings of at least 5, optimally at least 9.

Coefficient of Friction

30 Coefficient of friction (COF) is a measurement of lubricity of a coating and is used to give an indication of how a cured coating will perform on commercial fabrication equipment and presses. Typically, lubricants are added to coatings requiring aggressive post application fabrication to give the appropriate lubricity.

For the present evaluation, an Altek Mobility / Lubricity Tester Model 9505AE with a chart recorder was used to measure the COF of cure beverage end coatings on aluminum substrates. The instrument works by pulling a sled with steel balls attached to a loadbar across the surface of the coated substrate, and the COF is charted out as resistance on 0-10 scale chart paper. Each unit equals 0.25 COF units. Coatings of the present invention are formulated to give a preferred COF range of 0.055 to 0.095.

Fabrication or End Continuity

This test measures the ability of a coated substrate to retain its integrity as it undergoes the formation process necessary to produce a beverage can end. It is a measure of the presence or absence of cracks or fractures in the formed end. The end is typically placed on a cup filled with an electrolyte solution. The cup is inverted to expose the surface of the end to the electrolyte solution. The amount of electrical current that passes through the end is then measured. If the coating remains intact (no cracks or fractures) after fabrication, minimal current will pass through the end.

For the present evaluation, fully converted 202 standard opening beverage ends were exposed for a period of 4 seconds to an electrolyte solution comprised of 1% NaCl by weight in deionized water. Metal exposure was measured using a WACO Enamel Rater II, available from the Wilkens-Anderson Company, Chicago, IL, with an output voltage of 6.3 volts. The measured electrical current, in milliamps, is reported. End continuities are typically tested initially and then after the ends are subjected to pasteurization or retort.

Preferred coatings of the present invention initially pass less than 10 milliamps (mA) when tested as described above, more preferably less than 5 mA, most preferably less than 2 mA, and optimally less than 1 mA. After pasteurization or retort, preferred coatings give continuities of less than 20 mA, more preferably less than 10 mA, even more preferably less than 5 mA, and even more preferably less than 2 mA.

Example 1: Run 1. Preparation of Acid-Functional Acrylic

A premix of 512.6 parts glacial methacrylic acid (MAA), 512.6 parts butyl acrylate (BA), 114.0 parts styrene, and 73.2 parts benzoyl peroxide (70% water wet) was prepared in a separate vessel. A 3-liter flask was equipped with a stirrer, reflux condenser, thermocouple, heating mantle, and nitrogen blanket. Ten percent of the premix was added to the flask along with 405.9 parts butanol and 30.6 parts deionized water. To the remaining premix were added 496.1 parts butanol and 38.3 parts deionized water. With the nitrogen blanket flowing in the flask, the contents were heated to 93°C. At 93°C, external heating was stopped and the material was allowed to increase in temperature for fifteen minutes. After fifteen minutes, the batch was at 97°C, and the remaining premix was added uniformly over two hours maintaining 97°C to 100°C. When the premix addition was complete, the premix vessel was rinse with 5 parts butanol. The batch was held at temperature for two and a half hours. The heating was discontinued and 317.7 parts butyl Cellosolve (ethylene glycol monobutyl ether) was added. The resulting acrylic prepolymer was 44.3% solids (NV), with an acid number of 313 and a Brookfield viscosity (as determined by ASTM D-2196) of 4,990 centipoise (cps).

Example 1: Run 2. Preparation of Acid-Functional Acrylic

A premix of 677.7 parts glacial methacrylic acid, 677.7 parts butyl methacrylate (BMA), 150.8 parts styrene, and 96.9 parts benzoyl peroxide (70% water wet) was prepared in a separate vessel. A 5-liter flask was equipped with a stirrer, reflux condenser, thermocouple, heating mantle, and nitrogen blanket. Ten percent of the premix was added to the flask along with 536.9 parts butanol and 40.7 parts deionized water. To the remaining premix were added 758.1 parts butanol and 50.6 parts deionized water. With the nitrogen blanket flowing in the flask, the contents were heated to 93°C. At 93°C, external heating was stopped, and the material was allowed to increase in temperature for ten minutes. After ten minutes, the batch was at 98°C, and the remaining premix was added uniformly over two hours maintaining 97°C to 100°C. The batch was held at temperature for three hours. The heating was discontinued and the batch cooled. The resulting acrylic prepolymer was 49.9% NV, with an acid number of 304 and a Brookfield viscosity of 101,000 centipoise.

Example 1: Run 3. Preparation of Acid-Functional Acrylic

A premix of 802.6 parts glacial methacrylic acid, 807 parts butyl methacrylate, 178.5 parts styrene, 80.3 parts t-butyl peroctoate, 838.5 parts butanol, and 59.9 parts deionized water was prepared in a separate vessel. A 5-liter flask was equipped with a stirrer, reflux condenser, thermocouple, heating mantle, and nitrogen blanket. Added to the 5 liter flask were 635.8 parts butanol and 48.1 parts deionized water. The flask was heated to 94°C. At 94°C 12.5 parts t-butyl peroctoate were added. The batch was held for five minutes after which the premix was added over two and a half hours. A second premix containing 59.2 parts butanol and 16.1 parts t-butyl peroctoate was prepared. When the addition of the first premix was complete the second premix was added over 30 minutes. Once complete, the batch was held for 30 minutes. A chase of 3.4 parts t-butyl peroctoate was added and the batch held for two hours. After the two-hour hold time, the heat was discontinued and the batch cooled. The resulting acrylic prepolymer was 50.1% NV, with an acid number of 292 and a Brookfield viscosity of 150,000 centipoise.

Example 1: Run 4. Preparation of Acid-Functional Acrylic

A premix of 802.6 parts glacial methacrylic acid, 445.9 parts ethyl acrylate, 535.1 parts styrene, 108.6 parts t-butyl peroctoate, 838.5 parts butanol, and 59.9 parts deionized water was prepared in a separate vessel. A 5-liter flask was equipped with a stirrer, reflux condenser, thermocouple, heating mantle, and nitrogen blanket. Added to the 5-liter flask was 635.8 parts butanol and 48.1 parts deionized water. The flask was heated to 94 °C. At 94 °C 16.6 parts t-butyl peroctoate was added. The batch was held for five minutes after which the premix was added over two and a half hours. A second premix containing 59.2 parts butanol and 21.2 parts t-butyl peroctoate was prepared. When the addition of the first premix was complete the second premix was added over 30 minutes. Once complete, the batch was held for 30 minutes. A chase of 4.6 parts t-butyl peroctoate was added and the batch held for two hours. After the two hour hold the heat discontinued and the batch cooled. The resulting acrylic prepolymer was 49.8% NV, with an acid number of 303 and a Brookfield viscosity of 21,650 centipoise.

Example 1: Runs 5-11

Using techniques from Example 1: Run 4, the systems shown in Table 1 were prepared.

Table 1: Acid-Functional Acrylics

5 ¹ Glacial acrylic acid

² Hydroxypropyl methacrylate

Example 1: Run 12. Preparation of Acid-Functional Acrylic

10 A premix of 803.4 parts glacial methacrylic acid, 446.3 parts ethyl acrylate (EA), 535.5 parts styrene, 153 parts benzoyl peroxide (70% water wet), 839.2 parts butanol, and 60 parts deionized water was prepared in a separate vessel. A 5-liter flask was equipped with a stirrer, reflux condenser, thermocouple, heating mantle and nitrogen blanket. To the flask, 636.3 parts butanol and 48.2 parts deionized water were added and heated to 97°C to 100°C with a nitrogen blanket flowing in the flask. The premix was added uniformly over two and a half hours maintaining 97°C to 100°C. When the premix was in, the premix vessel was rinsed with 59.2 parts butanol and added to the flask. The batch was held at temperature for two hours. The heating was discontinued and the batch cooled. The resulting acrylic prepolymer was 50.2% NV, with an acid number of 301 and a Brookfield viscosity of 25,400 centipoise.

15

20

Example 1: Runs 13-15

Using techniques from Example 1: Run 12 the systems shown in Table 2 were prepared.

5

Example 2: Run 1. Preparation of Salt of Acid-Functional Acrylic

A 3-liter flask was equipped with a stirrer, reflux condenser, Dean Stark Tube, thermocouple, heating mantle, and nitrogen blanket. Into the flask was added 711.5 parts of Example 1: Run 1 acrylic, 762.9 parts deionized water, and 56.9 parts dimethyl ethanol amine (DMEA). The contents were heated to reflux and 553 parts were distilled from the flask. After distillation was complete, 598 parts of deionized water were added. The batch was cooled giving an acrylic solution at 20.3% solids and 307 acid number.

10
15

Example 2: Run 2. Preparation of Salt of Acid-Functional Acrylic

A 5-liter flask was equipped with a stirrer, reflux condenser, Dean Stark Tube, thermocouple, heating mantle, and nitrogen blanket. Into the flask was added 1853 parts of Example 1: Run 2 acrylic, 2220.4 parts deionized water, and 163.3 parts dimethyl ethanol amine. The contents were heated to reflux and 1587 parts were distilled from the flask. After distillation was complete, 1718 parts of deionized water were added. The batch was cooled giving an acrylic solution at

20

22.2% solids, 294 acid number, pH of 6.0, and a viscosity of 13 seconds (#4 Ford cup viscosity as determined by ASTM D-1200).

Example 2: Run 3. Preparation of Salt of Acid-Functional Acrylic

5 A 5-liter flask was equipped with a stirrer, reflux condenser, Dean Stark Tube, thermocouple, heating mantle, and nitrogen blanket. Into the flask was added 1852.3 parts of Example 1: Run 3 acrylic, 2219 parts deionized water, and 163 parts dimethyl ethanol amine. The contents were heated to reflux and 1463 parts were distilled from the flask. After distillation was complete, 1581 parts of deionized
10 water were added. The batch was cooled giving an acrylic solution at 21.6% solids, 284 acid number, pH of 6.23 and a viscosity of 13 seconds (#4 Ford cup).

Example 2: Run 4. Preparation of Salt of Acid Functional Acrylic

A 5-liter flask was equipped with a stirrer, reflux condenser, Dean Stark
15 Tube, thermocouple, heating mantle, and nitrogen blanket. Into the flask was added 1799.2 parts of Example 1: Run 4 acrylic, 2155.9 parts deionized water, and 158.6 parts dimethyl ethanol amine. The contents were heated to reflux and 1541 parts were distilled from the flask. After distillation was complete, 1615 parts of deionized water were added. The batch was cooled giving an acrylic solution at
20 22.1% solids, 302 acid number, pH of 6.55 and a Brookfield viscosity of 2060 centipoise.

Example 2: Runs 5-9

Using techniques from Example 2: Run 4 the systems shown in Table 3 were
25 prepared. Each run of Example 2 used the correspondingly numbered run from Example 1. That is, Example 2: Run 5 used the acrylic prepolymer from Example 1: Run 5.

30

Example 3: Run 1. Emulsion

5 A 1-liter flask was equipped with a stirrer, reflux condenser, thermocouple, heating mantle, and nitrogen blanket. Into the flask were added 313.9 parts of Example 2: Run 3 salt and 267.3 parts deionized water. The contents of the flask were heated to 75°C at 280 revolutions per minute (RPM). In a separate vessel, a premix of 71.4 parts styrene, 116.3 parts butyl methacrylate, and 16.3 parts glycidyl methacrylate (GMA) was prepared. Once the flask was at 75°C, 10% of the premix was added followed by 2.04 parts benzoin and 20 parts deionized water. The flask was heated further to 79°C. At 79°C, 2.04 parts of 35% hydrogen peroxide was added and held for five minutes. After five minutes the temperature control was set at 81°C and the remaining premix was added over a period of one hour. When the addition was complete, 20 parts deionized water were used to rinse the residual premix into the flask. The batch was held for ten minutes and then 0.35 part benzoin, 20 parts deionized water, and 0.35 part 35% hydrogen peroxide were added. After two hours the heat was removed and the batch cooled. This gave an emulsion at 31.9% solids, 63.3 acid number, pH of 6.48, and a Brookfield viscosity of 203 centipoise.

10

15

20

Example 3: Run 2. Emulsion

A 0.5-liter flask was equipped with a stirrer, reflux condenser, thermocouple, heating mantle, and nitrogen blanket. Into the flask was added 155.6 parts of Example 2: Run 4 salt and 120.6 parts deionized water. The contents of the flask
5 were heated to 75°C at 240 RPM. In a separate vessel, a premix of 66.3 parts styrene, 19.6 parts ethyl acrylate, and 7.5 parts glycidyl methacrylate was prepared. Once the flask was at 75°C, 10% of the premix was added followed by 0.91 part benzoin and 9.4 parts deionized water. The flask was heated further to 79°C. At 79°C, 0.91 part of 35% hydrogen peroxide was added and held for five minutes.
10 After five minutes the temperature control was set at 81°C and the remaining premix was added over one hour. When the addition was complete, 9.4 parts deionized water were used to rinse the residual premix into the flask. The batch was held for ten minutes and then 0.16 part benzoin, 9.4 parts deionized water, and 0.16 part 35% hydrogen peroxide were added. After two hours the heat was removed and the batch
15 cooled. This gave an emulsion at 30.9% solids, 83.8 acid number, pH of 6.70, and a viscosity of 40 seconds (#4 Ford cup).

Example 3: Run 3. Emulsion

A 1-liter flask was equipped with a stirrer, reflux condenser, thermocouple,
20 heating mantle, and nitrogen blanket. Into the flask was added 311.2 parts of Example 2: Run 4 salt and 241.2 parts deionized water. The contents of the flask were heated to 75°C at 270 RPM. In a separate vessel, a premix of 112.1 parts styrene, 59.8 parts ethyl acrylate, and 14.9 parts glycidyl methacrylate was prepared. Once the flask was at 75°C, 10% of the premix was added followed by 1.87 parts
25 benzoin and 18.8 parts deionized water. The flask was heated further to 79°C. At 79°C, 1.87 parts of 35% hydrogen peroxide were added and held for five minutes. After five minutes, the temperature control was set at 81°C and the remaining premix was added over one hour. When the addition was complete, 18.8 parts deionized water were used to rinse the residual premix into the flask. The batch was
30 held for ten minutes and then 0.32 part benzoin, 18.8 parts deionized water, and 0.32 part 35% hydrogen peroxide were added. After two hours, the heat was removed and the batch cooled. This gave an emulsion at 31.8% solids, 76.7 acid number, pH of 6.67, and a viscosity of 28 seconds (#4 Ford cup).

Example 3: Run 4. Emulsion

A 5-liter flask was equipped with a stirrer, reflux condenser, thermocouple, heating mantle, and nitrogen blanket. Into the flask was added 1525.0 parts of Example 2: Run 4 salt and 1219.1 parts deionized water. The contents of the flask were heated to 70°C at 250 RPM. In a separate vessel a premix of 380.4 parts styrene, 278.3 parts butyl acrylate (BA), 194.9 parts butyl methacrylate, and 74.2 parts glycidyl methacrylate was prepared. Once the flask was at 70°C, 10% of the premix was added followed by 9.29 parts benzoin and 92.9 parts deionized water. The flask was heated further to 79°C. At 79°C, 9.29 parts of 35% hydrogen peroxide were added and held for five minutes. After five minutes the temperature control was set at 81°C and the remaining premix was added over one hour. When the addition was complete, 92.9 parts deionized water were used to rinse the residual premix into the flask. The batch was held for ten minutes and then 1.59 parts benzoin, 92.9 parts deionized water, and 1.59 parts 35% hydrogen peroxide were added. The batch was held for 45 minutes and then 0.52 part benzoin and 0.52 part 35% hydrogen peroxide were added. After two hours the heat was removed and the batch cooled. This gave an emulsion at 31.4% solids, 64.1 acid number, pH of 6.95, and a viscosity of 22 seconds (#4 Ford cup).

Example 3: Run 5. Emulsion

A 12-liter flask was equipped with a stirrer, reflux condenser, thermocouple, heating mantle, and nitrogen blanket. Into the flask was added 3886.5 parts of Example 2: Run 4 salt and 3022.5 parts deionized water. The contents of the flask were heated to 70°C at 235 RPM. In a separate vessel, a premix of 771.25 parts styrene, 933.75 parts butyl acrylate, 537.5 parts butyl methacrylate, and 93.75 parts glycidyl methacrylate was prepared. Once the flask was at 70°C, 23.38 parts benzoin and 116.25 parts deionized water followed by 10% of the premix were added. The flask was heated further to 79°C. At 79 °C, 23.38 parts of 35% hydrogen peroxide and 116.25 parts deionized water were added and held for five minutes. After five minutes the temperature control was set at 81°C and the remaining premix was added over one hour. When the addition was complete, 232.5 parts deionized water were used to rinse the residual premix into the flask. The batch was held for ten minutes and then 4.0 parts benzoin, 232.5 parts deionized water, and 4.0 parts 35%

hydrogen peroxide were added. The batch was held for 45 minutes and then 1.25 parts benzoin and 1.25 parts 35% hydrogen peroxide were added. After two hours the heat was removed and the batch cooled. This gave an emulsion at 31.4% solids, 72.4 acid number, pH of 7.05, and a viscosity of 32 seconds (#4 Ford cup).

5

Example 3: Runs 6-10

Using the process outlined in Example 3: Run 4 the Emulsions shown in Table 4 were prepared.

10

Table 4: Emulsions

Example 3:	Run 4	Run 6	Run 7	Run 8	Run 9	Run 10
Acrylic salt	Ex. 2: Run 4	Ex. 2: Run 4	Ex. 2: Run 4	Ex. 2: Run 4	Ex. 2: Run 4	Ex. 2: Run 4

The following are some of the conclusions drawn from results of the emulsion DOEs shown in Tables 5 through 10. The non styrene-containing acrylic stabilizer polymer from Example 2: Run 9 produced higher viscosity emulsions, which are less desirable. The stabilizer acrylic polymer composition from Example 2: Run 4 gave better overall film performance. The higher acrylic polymer / monomer ratio tended to give poorer film integrity (continuities), so minimization of the acrylic stabilizer level is necessary. Higher GMA levels in the emulsion monomer mix tended to give higher emulsion viscosities and greater increases in film continuity mAs after retort, so lower levels are better. Little difference was noticed between the various co-monomer compositions, so there is latitude to vary the overall emulsion monomer composition.

Example 3: Runs 34-35

A series of emulsions, shown in Table 11 were prepared using a monomer to acid functional acrylic ratio of 73/27 solids/solids. These systems were prepared using the process outlined in Example 3: Run 5 using Example 2: Run 4 as the acid functional acrylic salt.

Table 11: Emulsion GMA Level Study

Example 3:	Run 5	Run 34	Run 35
GMA Level	4%	12%	20%
Monomers			
Styrene	33	33	33
BA	40	42	44
BMA	23	13	3
GMA	4	12	20
Solids	31.6%	31.8%	32.0%
Viscosity (#4 Ford cup)	50 sec	---	---
Brookfield Visc. (cps)	---	1,070	33,950
Acid Number	69.0	59.5	44.9

It can be seen that as the glycidyl methacrylate level increased the resulting acid number decreased indicating the GMA consumed some of the acid groups on the acrylic polymer stabilizer.

5

Example 3: Runs 36-42

A series of emulsions, shown in Table 12, were prepared using a monomer to acid functional acrylic ratio of 73/27 solids/solids. These systems were prepared using the process outlined in Example 3: Run 5 using Example 2: Run 10 as the acid functional acrylic salt. This acrylic contains hydroxyl functionality to co-react with the IBMA during cure.

10

Table 12: Effect of IBMA in Emulsions

Example 3:	Run 36	Run 37	Run 38	Run 39	Run 40	Run 41	Run 42

Acid Number	38.1	40.1	40.9	39.5	40.5	41.0	40.4

[†] N-Isobutoxymethyl acrylamide

15

The latices from Table 12 were tested without further modification or formulation, and the results are shown in Table 13. Each composition was drawn down onto Alcoa ALX aluminum at a film weight of 7-8 msi and cured for 10 seconds at 420°F (215°C) peak metal temperature in a gas fired coil oven.

20

Table 13: Beverage End Continuities (IBMA Level)

Example 3:	Run 36	Run 37	Run 38	Run 39	Run 40	Run 41	Run 42
IBMA Level	0%	4%	5%	6%	7%	8%	12%
End Continuity							
Initial	3	1.5	1.1	1.0	0.4	0.9	0.7
After Retort ¹	19	12	4.3	6.5	6.6	9.3	31

¹ 90 minutes at 250°F (121°C).

Results from Table 13 indicate the optimum level of IBMA in the emulsion monomer composition is around 5%, when used in conjunction with hydroxyl functionality in the acrylic polymer stabilizer.

Example 4: Runs 1-2. Spray Application

The water-based emulsion of Example 3: Run 4 was successfully formulated into a spray applied coating for the interior of beer/beverage aluminum cans. The product was formulated with or without additional surfactant as described in Table 14.

Table 14: Beverage Inside Spray Coating Compositions

Example 4:	Run 1	Run 2
Composition (parts)		
Example 3: Run 4	62	65
Butanol	6	5
Butyl Cellosolve	3	0
Amyl Alcohol	1	0

Global extraction ²	0.25 ppm	3.8 ppm

¹ 90 minutes at 250°F (121°C).

² 2 hours at 150°F in 90% aqueous ethanol.

The cured films displayed excellent resistance properties and low global extractions despite the fact that their solvent resistance as determined by MEK rubs is low. The higher global extraction result for Example 4: Run 2 was determined to be due to the surfactant present.

Example 4: Runs 3-4. Spray Application

The water-based emulsion of Example 3: Run 4 and Example 3: Run 7 were successfully formulated into spray applied coatings for the interior of beer/beverage aluminum cans. Coating compositions are shown in Table 16.

Table 16: Inside Spray Coating Compositions

Example 4:	Run 3	Run 4

Global extractions ³	<0.1 ppm ⁴	<0.1 ppm ⁴	<0.1 ppm ⁴

¹ Commercially available inside beverage can coating from Valspar coded 10Q45AF.

² 90 minutes at 250°F (121°C).

³ 2 hours at 150°F in 90% aqueous ethanol.

⁴ Below the detection limit.

As can be seen in Table 17, the coatings of the present invention show at least equivalent performance to the commercial epoxy-acrylate coating, and there is a substantial benefit for retort resistance.

Example 5: Run 1. Beverage End Coil Coating

In a one quart jar with an agitator, 483.25 parts of Example 3: Run 5 emulsion was stirred with 16.75 parts SLIPAYD 404 wax available from Elementis DPC Inc. The mixture was stirred for 10 minutes to make it uniform. The mixture was then filtered. The mixture was approximately 31% solids. The mixture was applied at 7-8 milligrams per square inch (msi) on ALX Alcoa aluminum and baked for 10 seconds (sec) at 400°F (205°C) in a coil oven. It was also applied at 7-8 msi on ALX Alcoa aluminum and baked for 10 seconds and 435°F (224°C) in a coil oven. Film properties are shown in Table 18.

Table 18: Beverage End Film Properties

	Waterbased Control ¹				Example 5 Run 1			
Bake	10 sec @ 400°F		10 sec @ 435°F		10 sec @ 400°F		10 sec @ 435°F

¹ Commercially available beverage end coating Valspar coded 10Q80AG.

² Performed after a 45 minutes at 85°C (185°F) pasteurization. Measured in inches.

³ 15 minutes at 100°C (212°F).

⁴ 30 minutes at 85°C (185°F).

⁵ 90 minutes at 121°C (250°F).

Example 5: Runs 2-4 Beverage End Coatings

Using the process of Example 5: Run 1, the formulations shown in Table 19 were prepared to investigate the effect of GMA level on end continuities. Each formula was applied at 7-8 milligrams per square inch (msi) on ALX Alcoa aluminum and baked for 10 seconds at 420°F (215°C) in a coil oven. End continuities are shown in Table 20.

Table 19: Effect of GMA Level

Example 5:	Run 2	Run 3	Run 4
Example 3 Run 5	95.7	0	0
Example 3 Run 34	0	95.7	0
Example 3 Run 35	0	0	95.7
Phenolic ¹	2.3	2.3	2.3
SLIPAYD 404	1.5	1.5	1.5
Michem Lube 160 PFE ²	0.5	0.5	0.5
Water/Solvent ³	To 23% Solids	To 23% Solids	--
Deionized Water	--	--	To 23% Solids

¹ A phenol-formaldehyde phenolic at 50% in water, prepared by reacting 2.3 moles of formaldehyde with 1 mole of phenol.

² Commercially available lubricant from Michelman Inc.

5 ³ 1:1 Blend of deionized water and isopropyl alcohol.

Table 20: Effect of GMA Level on Beverage End Performance

Example 5:	Run 2	Run 3	Run 4
GMA Level	4%	12%	20%
End Continuities			
Initial	2	49	149
After Retort ¹	21	193	304

¹ 90 minutes at 121°C (250°F).

10 As can be seen by the data in Table 20, lower GMA levels lead to better film integrity on fabricated ends, especially after a retort. Thus, about 4% GMA in the emulsion monomer composition is a preferred level.

Example 5: Run 5 Beverage End Coating

15 Using the process of Example 5: Run 1, the formulation shown in Table 21 was prepared. The formula was applied at 7-8 milligrams per square inch (msi) on ALX Alcoa aluminum and baked for 10 seconds at 400°F (204°C) and 420°F (215°C) in a coil oven. Film and end performance properties are shown in Table 22. This material contains 4% GMA and 5% IBMA in the emulsion monomer mix and an optimized acrylic composition with hydroxyl functionality.

5 ¹ Commercially available beverage end coating as from Valspar coded 10Q80AG.

² 30 minutes at 85°C (185°F).

³ 90 minutes at 121°C (250°F).

⁴ Performed after 45 minutes at 85°C (185°F) pasteurization. Measured in inches.

Results from Table 22 show an optimized beverage end formulation of the present invention gives similar performance to a commercial epoxy-based waterborne beverage end coating even with lower solvent resistance as measured by MEK double rubs. There is also added benefit of improved feathering resistance.

5

Example 6: Latex with Polyester Stabilizer

Example 6 is designed to illustrate the use of a different acid-functional polymer salt as the stabilizer for an emulsion of the present invention.

10 Stage A

A 2-liter flask was equipped with a stirrer, packed column, Dean Stark trap, reflux condenser, thermocouple, heating mantle and nitrogen blanket. To the flask 700.1 parts dipropylene glycol and 700.1 parts isophthalic acid were added. Under a nitrogen blanket, the contents were heated to 125°C. At 125°C, 1.05 parts Fascat
15 4201 (available from Atofina) was added. The temperature was increased to remove water. At 210°C, water was beginning to collect. After an acid number of 5.2 was obtained, 37 parts of xylene was added to aid in the removal of water. An acid number of 0.9 was obtained, and a portion of the product was used in Stage B.

20 Stage B

The material from Stage A (599.8 parts) was placed in a 2-liter flask. The temperature was set at 112°C and 82 parts trimellitic anhydride was added. The material was heated to 232°C, and water was removed. After an acid number of 48.4 was obtained, a portion of the material was used in Stage C.

25

Stage C

The material from Stage B (198.8 parts) was added to a 2-liter flask, and 40 parts of DOWANOL PnP were added. The material was adjusted to 74°C, and slow addition of deionized water (200 parts) was initiated. After about 30 parts of water
30 were added, 7.6 parts dimethyl ethanolamine were introduced. When about 150 parts of the deionized water were in, heating was halted (the temperature was at 80°C) and 2.4 parts dimethyl ethanolamine were added. After the entire charge of deionized

water was complete, the viscosity was visually high and 200 additional parts deionized water was added. The material was allowed to slowly cool while additional dimethyl ethanolamine was added incrementally to increase the pH to 6.6. The resulting product was 29.7% solids with an acid number of 53.9.

5

Stage D

A 500-milliliter flask was equipped with a stirrer, reflux condenser, thermocouple, heating mantle, and nitrogen blanket. Into the flask was added 93.2 parts of the Stage C material and 179 parts deionized water. While the contents of the flask were being heated to 50°C at 240 RPM, 2 drops of HAMP-OL 4.5% Iron (Commercially available from W.R. Grace) and 1.11 parts erythorbic acid were added. In a separate vessel a premix of 28.8 parts styrene, 50.9 BA, 21.0 parts BMA, 5.6 parts IBMA, 4.5 parts GMA and 1.11 parts Trigonox A-W70 (Commercially available from AKZO Chemical) were premixed. Once the flask was at 52°C, 10% of the premix was added and held for five minutes. After five minutes, the temperature control was set for 50°C and the remaining premix was added over one hour. When the addition was complete, 15.0 parts deionized water was used to rinse the residual premix into the flask. The batch was then held for two hours at temperature, and the batch was cooled. This yielded an emulsion at 34.0% solids, 14.5 acid number, pH of 5.45, and a viscosity 11.5 sec (#4 Ford Cup).

10
15
20

Stage E

To 50 parts of the emulsion from Stage D, 3.125 parts of a 50/50 blend of ethylene glycol and butyl cellosolve was added. This material was applied to chrome treated aluminum panels and baked for 10 seconds at 420°F (217°C). Results from beverage end testing versus a commercial control formula are shown in Table 23.

10 The complete disclosures of the patents, patent documents, and publications
cited herein are incorporated by reference in their entirety as if each were
individually incorporated. Various modifications and alterations to this invention
will become apparent to those skilled in the art without departing from the scope and
spirit of this invention. It should be understood that this invention is not intended to
be unduly limited by the illustrative embodiments and examples set forth herein and
15 that such examples and embodiments are presented by way of example only with the
scope of the invention intended to be limited only by the claims set forth herein as
follows.

What is claimed is:

1. A method of coating a food or beverage can, the method comprising:
forming a composition comprising an emulsion polymerized latex polymer,
comprising:
5 forming a salt of an acid- or anhydride-functional polymer and an
amine in a carrier comprising water to form an aqueous dispersion;
combining an ethylenically unsaturated monomer component with the
aqueous dispersion; and
polymerizing the ethylenically unsaturated monomer component in
10 the presence of the aqueous dispersion to form an emulsion polymerized
latex polymer; and
applying the composition comprising the emulsion polymerized latex
polymer to a metal substrate prior to or after forming the metal substrate into a food
or beverage can or portion thereof.
15
2. The method of claim 1 wherein applying the composition to a metal substrate
comprises applying the composition to the metal substrate in the form of a planar
coil or sheet, hardening the emulsion polymerized latex polymer, and forming the
substrate into a food or beverage can or portion thereof.
20
3. The method of claim 2 wherein forming the substrate into a can or portion
thereof comprises forming the substrate into a can end or a can body.
4. The method of claim 2 wherein the can is a 2-piece drawn food can, 3-piece
25 food can, food can end, drawn and ironed can, beverage can end, and the like.
5. The method of claim 1 wherein the metal substrate comprises steel or
aluminum.
- 30 6. The method of claim 1 wherein applying the composition to a metal substrate
comprises applying the composition to the metal substrate after the metal substrate is
formed into a can or portion thereof.

7. The method of claim 1 wherein combining an ethylenically unsaturated monomer component with the aqueous dispersion comprises adding the ethylenically unsaturated monomer component to the aqueous dispersion.
- 5
8. The method of claim 7 wherein the ethylenically unsaturated monomer component is added incrementally to the aqueous dispersion.
9. The method of claim 1 wherein the ethylenically unsaturated monomer component comprises a mixture of monomers.
- 10
10. The method of claim 9 wherein the mixture of monomers comprises at least one oxirane functional group-containing monomer.
11. The method of claim 10 wherein the mixture of monomers comprises at least one oxirane functional group-containing alpha, beta-ethylenically unsaturated monomer.
- 15
12. The method of claim 10 wherein the oxirane functional group-containing monomer is present in the ethylenically unsaturated monomer component in an amount of at least 0.1 wt-%, based on the weight of the monomer mixture.
- 20
13. The method of claim 10 wherein the oxirane functional group-containing monomer is present in the ethylenically unsaturated monomer component in an amount of no greater than 30 wt-%, based on the weight of the monomer mixture.
- 25
14. The method of claim 1 further comprising combining the emulsion polymerized latex polymer with one or more crosslinkers, fillers, catalysts, dyes, pigments, toners, extenders, lubricants, anticorrosion agents, flow control agents, thixotropic agents, dispersing agents, antioxidants, adhesion promoters, light stabilizers, organic solvents, surfactants, or combinations thereof in the coating composition.
- 30

15. The method of claim 1 wherein acid-functional polymer has a number average molecular weight of 1500 to 50,000.
16. The method of claim 1 wherein the composition is substantially free of mobile BPA and aromatic glycidyl ether compounds.
17. The method of claim 16 wherein the composition is substantially free of bound BPA and aromatic glycidyl ether compounds.
18. The method of claim 1 wherein the acid- or anhydride-functional polymer comprises an acid- or anhydride-functional acrylic polymer, acid- or anhydride-functional alkyd resin, acid- or anhydride-functional polyester resin, acid- or anhydride-functional polyurethane, or combinations thereof.
19. The method of claim 18 wherein the acid- or anhydride-functional polymer comprises an acid-functional acrylic polymer.
20. The method of claim 1 wherein the amine is a tertiary amine.
21. The method of claim 20 wherein the tertiary amine is selected from the group consisting of trimethyl amine, dimethylethanol amine, methyldiethanol amine, triethanol amine, ethyl methyl ethanol amine, dimethyl ethyl amine, dimethyl propyl amine, dimethyl 3-hydroxy-1-propyl amine, dimethylbenzyl amine, dimethyl 2-hydroxy-1-propyl amine, diethyl methyl amine, dimethyl 1-hydroxy-2-propyl amine, triethyl amine, tributyl amine, N-methyl morpholine, and mixtures thereof.
22. The method of claim 1 wherein the acid- or anhydride-functional polymer is at least 25% neutralized with the amine in water.
23. The method of claim 1 wherein the ethylenically unsaturated monomer component is polymerized in the presence of the aqueous dispersion with a water-soluble free radical initiator at a temperature of 0°C to 100°C.

24. The method of claim 23 wherein the free radical initiator comprises a peroxide initiator.
- 5 25. The method of claim 24 wherein the free radical initiator comprises hydrogen peroxide and benzoin.
26. The method of claim 23 wherein the free radical initiator comprises a redox initiator system.
- 10 27. The method of claim 1 wherein the aqueous dispersion further comprises an organic solvent.
- 15 28. The method of claim 27 further comprising removing at least a portion of the organic solvent.
29. A method of coating a food or beverage can, the method comprising:
forming a composition comprising an emulsion polymerized latex polymer,
comprising:
20 forming a salt of an acid- or anhydride-functional polymer and a tertiary amine in a carrier comprising water to form an aqueous dispersion;
combining an ethylenically unsaturated monomer component
comprising 0.1 wt-% to 30 wt-% of an oxirane-functional alpha, beta-
ethylenically unsaturated monomer with the aqueous dispersion, based on the
25 weight of the monomer component; and
polymerizing the ethylenically unsaturated monomer component in
the presence of the aqueous dispersion to form an emulsion polymerized
latex polymer; and
applying the composition comprising the emulsion polymerized latex
30 polymer to a metal substrate prior to or after forming the metal substrate into a food or beverage can or portion thereof.

30. A food or beverage can prepared by the method of claim 1.
31. A food or beverage can prepared by the method of claim 29.
- 5 32. A food or beverage can comprising:
a body portion or an end portion comprising a metal substrate; and
a coating composition disposed thereon, wherein the coating composition
comprises an emulsion polymerized latex polymer, wherein the emulsion
polymerized latex polymer is prepared from a salt of an acid- or anhydride-
10 functional polymer and an amine, an ethylenically unsaturated monomer component,
and water.
33. The can of claim 32 wherein the ethylenically unsaturated monomer
component comprises a mixture of monomers.
- 15 34. The can of claim 33 wherein the mixture of monomers comprises at least one
oxirane functional group-containing monomer.
35. The can of claim 34 wherein the mixture of monomers comprises at least one
20 oxirane functional group-containing alpha, beta-ethylenically unsaturated monomer.
36. The can of claim 34 wherein the oxirane functional group-containing
monomer is present in the ethylenically unsaturated monomer component in an
amount of 0.1 wt-% to 30 wt-%, based on the weight of the monomer mixture.
- 25 37. The can of claim 31 wherein the acid- or anhydride-functional polymer
comprises an acid- or anhydride-functional acrylic polymer, acid- or anhydride-
functional alkyd resin, acid- or anhydride-functional polyester resin, acid- or
anhydride-functional polyurethane, or combinations thereof.
- 30 38. The can of claim 37 wherein the acid- or anhydride-functional polymer
comprises an acid-functional acrylic polymer.

39. The can of claim 31 wherein the amine is a tertiary amine.

40. A composition for use in coating a food or beverage can, the composition comprising an emulsion polymerized latex polymer, wherein the emulsion
5 polymerized latex polymer is prepared from a salt of an acid- or anhydride- functional polymer and an amine, an ethylenically unsaturated monomer component, and water.

10

COATING COMPOSITIONS FOR CANS AND METHODS OF COATING

Abstract of the Disclosure

5 A coating composition for a food or beverage can that includes an emulsion polymerized latex polymer formed by combining an ethylenically unsaturated monomer component with an aqueous dispersion of a salt of an acid- or anhydride-functional polymer and an amine, preferably, a tertiary amine.

10
